2019-nCoV Specific antibody IgM/IgG detection kit

(Colloidal gold method)

Introduction

When the human body is infected with the 2019-nCoV, the first antibody produced is the specific IgM antibody, which is generally produced after 3-7 days of infection, and is replaced by a large number of specific IgG antibodies produced about two weeks later. Therefore, IgM and IgG of the 2019-nCoV specific antibodies can be used as an auxiliary means for the diagnosis of suspected patients.

Product characteristics

The risk of medical staff is small, reducing the probability of droplet infection.

Dosage is less, only 1 drop of serum or plasma sample is needed.

It's fast and takes only 10 minutes to produce results.

Testing IgM and IgG at the same time to reduce the testing time.

No special testing environment and personnel training is required.

Convenient, fast, suitable for mass screening.

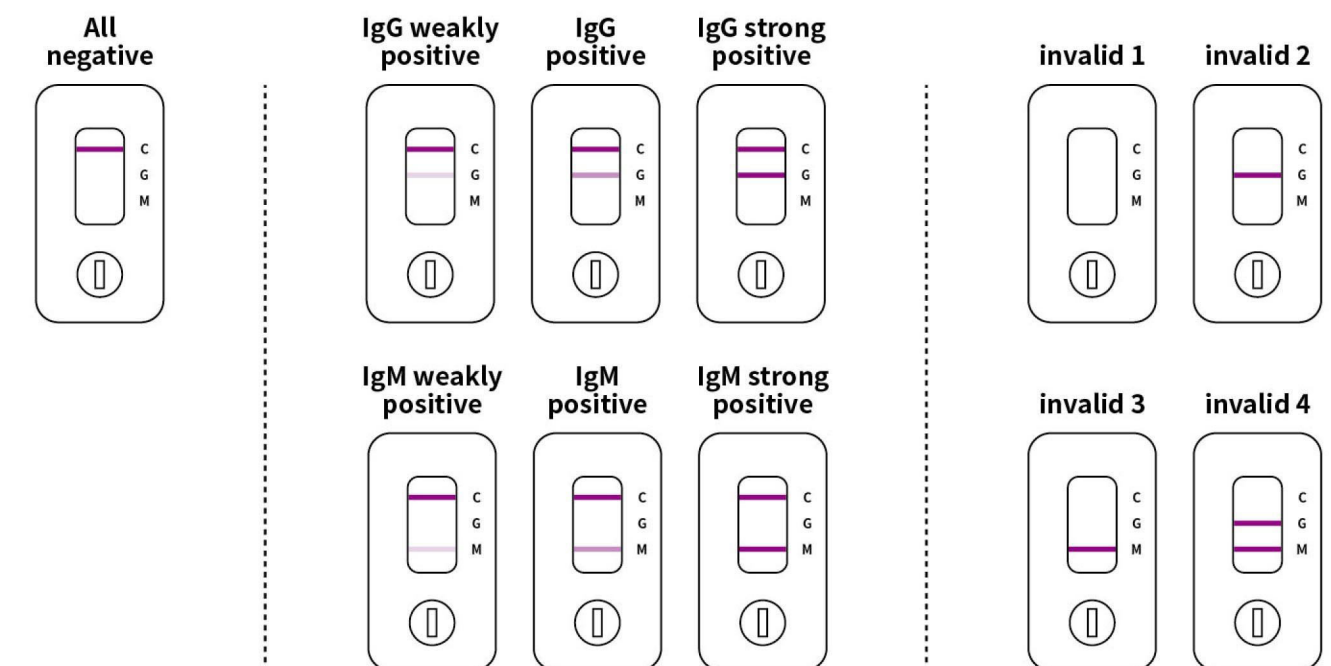

Compared with nucleic acid test swabs and pharyngeal swabs, it is less affected by samples and has high accuracy.

Adjuncts to confirm suspected cases
